Introduction to ANOVA for Statistics and Data Science
In this Lesson, we introduce Analysis of Variance or ANOVA. ANOVA is a statistical method that analyzes variances to determine if the means from more than two populations are the same. In other words, we have a quantitative response variable and a categorical explanatory variable with more than two levels. In ANOVA, the categorical explanatory is typically referred to as the factor.

In order to perform a one-way ANOVA test, there are five basic assumptions to be fulfilled: Each population from which a sample is taken is assumed to be normal. All samples are randomly selected and independent. The populations are assumed to have equal standard deviations (or variances).

One-way ANOVA is a test for differences in group means. One-way ANOVA is a statistical method to test the null hypothesis (H_0) that three or more population means are equal vs. the alternative hypothesis (H_a) that at least one mean is different. Using the formal notation of statistical hypotheses, for k means we write: $\$$

$H_0: \mu_1 = \mu_2 = \dots = \mu_k$ $\$$

Analysis of variance (ANOVA) is a statistical technique that is used to check if the means of two or more groups are significantly different from each other. ANOVA checks the impact of one or more factors by comparing the means of different samples. We can use ANOVA to prove/disprove if all the medication treatments were equally effective or not.
